Data Project Proposal

Due April 11thish Select a dataset that interests you. For the proposal, you need to answer the questions below.

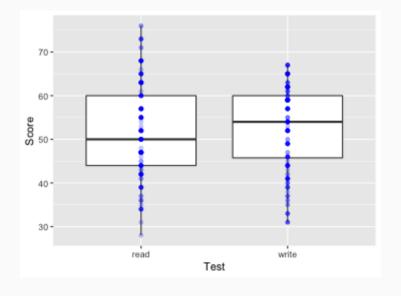

- Research question
- What type of statistical test do you plan to do (e.g. t-test, ANOVA, regression, logistic regression, chi-squared, etc.)
- What are the cases, and how many are there?
- Describe the method of data collection.
- What type of study is this (observational/experiment)?
- Data Source: If you collected the data, state self-collected. If not, provide a citation/link.
- Response: What is the response variable, and what type is it (numerical/categorical)?
- Explanatory: What is the explanatory variable(s), and what type is it (numerical/categorical)?
- Relevant summary statistics

More information including template and suggested datasets located here:

https://spring2021.data606.net/assignments/project/

High School & Beyond Survey

200 randomly selected students completed the reading and writing test of the High School and Beyond survey. The results appear to the right. Does there appear to be a difference?

Are the reading and writing scores of each student independent of each other?

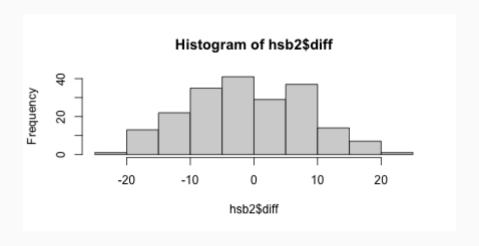

Analyzing Paired Data

- When two sets of observations are not independent, they are said to be paired.
- To analyze these type of data, we often look at the difference.

```
hsb2$diff <- hsb2$read - hsb2$write
head(hsb2$diff)</pre>
```

```
## [1] 5 9 11 19 -5 -8
```

hist(hsb2\$diff)

Setting the Hypothesis

What are the hypothesis for testing if there is a difference between the average reading and writing scores?

 H_0 : There is no difference between the average reading and writing scores.

$$\mu_{diff}=0$$

 H_A : There is a difference between the average reading and writing score.

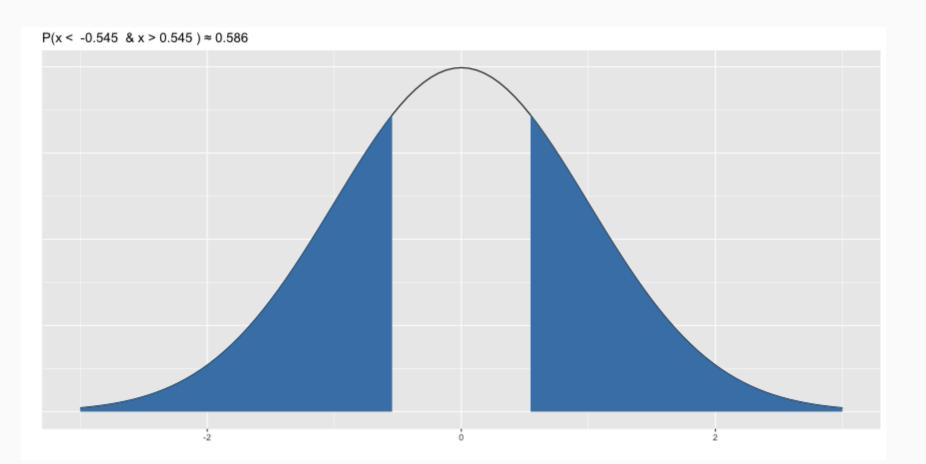

$$\mu_{diff}
eq 0$$

Nothing new here...

- The analysis is no different that what we have done before.
- We have data from one sample: differences.
- We are testing to see if the average difference is different that 0.

Calculating the test-statistic and the p-value

The observed average difference between the two scores is -0.545 points and the standard deviation of the difference is 8.8866664 points. Do these data provide confincing evidence of a difference between the average scores ont eh two exams (use $\alpha = 0.05$)?

Calculating the test-statistic and the p-value

$$Z = \frac{-0.545 - 0}{\frac{8.887}{\sqrt{200}}} = \frac{-0.545}{0.628} = -0.87$$

$$p-value = 0.1949 \times 2 = 0.3898$$

Since p-value > 0.05, we fail to reject the null hypothesis. That is, the data do not provide evidence that there is a statistically significant difference between the average reading and writing scores.

```
2 * pnorm(mean(hsb2$diff), mean=0, sd=sd(hsb2$diff)/sqrt(nrow(hsb2)))
```

```
## [1] 0.3857741
```

Evaluating the null hypothesis

Interpretation of the p-value

The probability of obtaining a random sample of 200 students where the average difference between the reading and writing scores is at least 0.545 (in either direction), if in fact the true average difference between the score is 0, is 38%.

Calculating 95% Confidence Interval

$$-0.545 \pm 1.96 \frac{8.887}{\sqrt{200}} = -0.545 \pm 1.96 \times 0.628 = (-1.775, 0.685)$$

Note that the confidence interval spans zero!

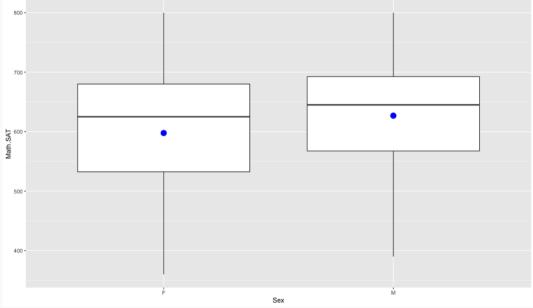

SAT Scores by Gender

```

                           M
```

Is there a difference in math scores between males and females?

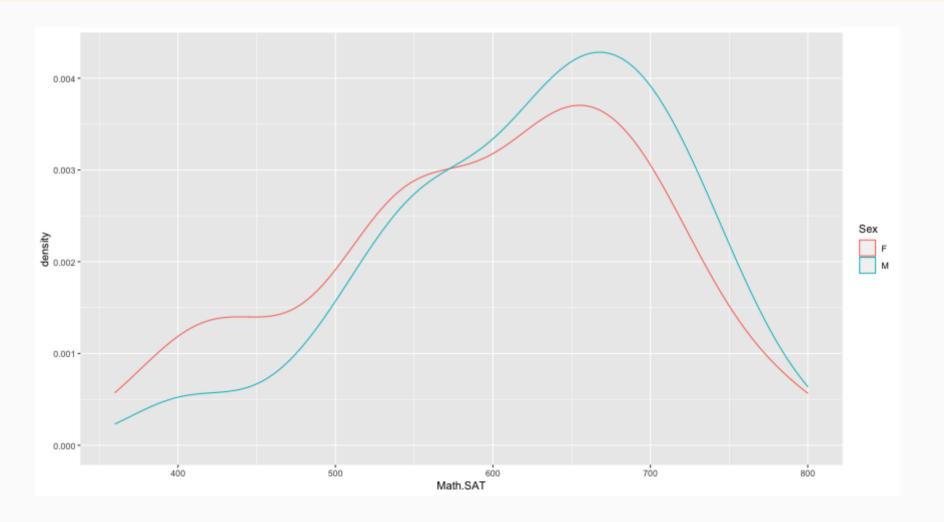

SAT Scores by Gender

```
## group1 n mean sd min
## X11 F 82 597.6829 103.70065 360
## X12 M 80 626.8750 90.35225 390
```

Distributions

```
ggplot(sat, aes(x=Math.SAT, color = Sex)) + geom_density()
```

95% Confidence Interval

We wish to calculate a 95% confidence interval for the average difference between SAT scores for males and females.

Assumptions:

- 1. Independence within groups.
- 2. Independence between groups.
- 3. Sample size/skew

Confidence Interval for Difference Between Two Means

- All confidence intervals have the same form: point estimate ± ME
- And all ME = critical value * SE of point estimate
- In this case the point estimate is $\bar{x}_1 \bar{x}_2$ Since the sample sizes are large enough, the critical value is z* So the only new concept is the standard error of the difference between two means...

Standard error of the difference between two sample means

$$SE_{(ar{x}_1-ar{x}_2)}=\sqrt{rac{s_1^2}{n_1}+rac{s_2^2}{n_2}}$$

Confidence Interval for Difference in SAT Scores

$$SE_{(ar{x}_1-ar{x}_2)} = \sqrt{rac{s_M^2}{n_M} + rac{s_F^2}{n_F}} = \sqrt{rac{90.4}{80} + rac{103.7}{82}} = 1.55$$

Student's t-Distribution

What if you want to compare the quality of one batch of Guinness beer to the next?

- Sample sizes necessarily need to be small.
- The CLT states that the sampling distribution approximates normal as n -> Infinity
- Need an alternative to the normal distribution.
- The *t* distribution was developed by William Gosset (under the pseudonym *student*) to estimate means when the sample size is small.

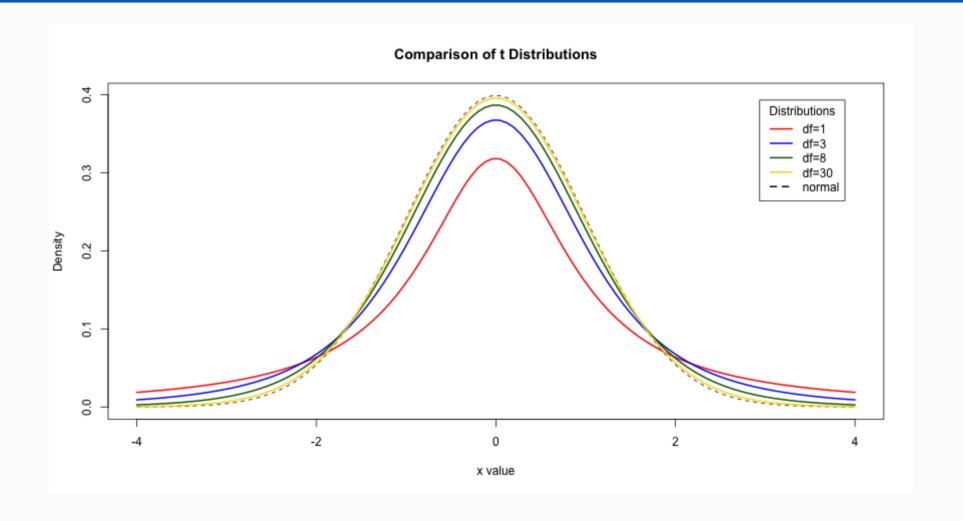

Confidence interval is estimated using

$$\overline{x}\pm t_{df}^{st}SE$$

Where df is the degrees of freedom (df = n - 1)

t-Distributions

t-test in R

The pt and qt will give you the p-value and critical value from the t-distribution, respectively.

Critical value for p = 0.05, degrees of freedom = 10

```
qt(0.025, df = 10)
```

```
## [1] -2.228139
```

p-value for a critical value of 2, degrees of freedom = 10

```
pt(2, df=10)
```

```
## [1] 0.963306
```

The t.test function will calculate a null hyphothesis test using the *t*-distribution.

```
t.test(Math.SAT ~ Sex, data = sat)
```

Analysis of Variance (ANOVA)

The goal of ANOVA is to test whether there is a discernible difference between the means of several groups.

Hand Washing Example

Is there a difference between washing hands with: water only, regular soap, antibacterial soap (ABS), and antibacterial spray (AS)?

- Each tested with 8 replications
- Treatments randomly assigned

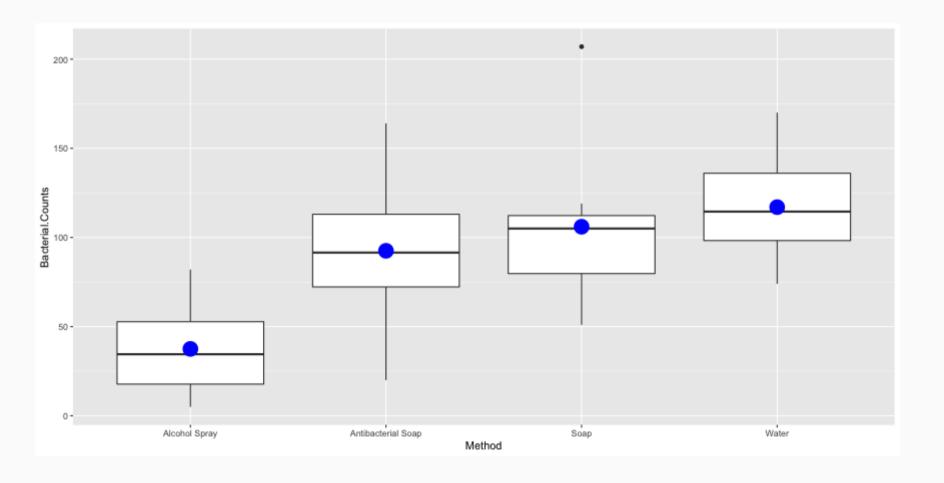

For ANOVA:

- The means all differ.
- Is this just natural variability?
- Null hypothesis: All the means are the same.
- Alternative hypothesis: The means are not all the same.

Hand Washing Comparison

```
ggplot(hand, aes(x=Method, y=Bacterial.Counts)) + geom_boxplot() +
    stat_summary(fun = mean, color = 'blue', size = 1.5)
```

Hand Washing Comparison (cont.)

[1] 2237.613

```
desc <- describeBy(hand$Bacterial.Counts, hand$Method, mat=TRUE, skew = FALSE)</pre>
desc$Var <- desc$sd^2</pre>
print(desc, row.names=FALSE)
  item
       group1 vars n mean sd min max range se Var
     1 Alcohol Spray 1 8 37.5 26.55991 5 82 77 9.390345 705.4286
  Soap 1 8 106.0 46.95895 51 207 156 16.602496 2205.1429
               Water 1 8 117.0 31.13106 74 170 96 11.006492 969.1429
mean(desc$Var)
## [1] 1410.143
var(hand$Bacterial.Counts)
```

Washing type all the same?

$$H_0: \mu_1 = \mu_2 = \mu_3 = \mu_4$$

Variance components we need to evaluate the null hypothesis:

- Between Sum of Squares: $SS_{between} = \sum_k n_k (\bar{x}_k \bar{x})^2$
- Within Sum of Squares: $SS_{within} = \sum_k \sum_i (\bar{x}_{ik} \bar{x}_k)^2$
- Between degrees of freedom: $df_{between} = k-1$ (k = number of groups)
- Within degrees of freedom: $df_{within} = k(n-1)$
- ullet Mean square between (aka treatment): $MS_T=rac{SS_{between}}{df_{between}}$
- ullet Mean square within (aka error): $MS_E=rac{SS_{within}}{df_{within}}$

Comparing MS_T (between) and MS_E (within)

Assume each washing method has the same variance.

Then we can pool them all together to get the pooled variance s_p^2

Since the sample sizes are all equal, we can average the four variances: $s_p^2=1410.14$

mean(desc\$Var)

[1] 1410.143

MS_T

- ullet Estimates s_p^2 if H_0 is true
- ullet Should be larger than s_p^2 if H_0 is false

MS_E

- ullet Estimates s_p^2 whether H_0 is true or not
- ullet If H_0 is true, both close to s_p^2 , so MS_T is close to MS_E

Comparing

- If H_0 is true, $rac{MS_T}{MS_E}$ should be close to 1
- If H_0 is false, $rac{MS_T}{MS_E}$ tends to be > 1

The F-Distribution

- How do we tell whether $\frac{MS_T}{MS_E}$ is larger enough to not be due just to random chance?
- $\frac{MS_T}{MS_E}$ follows the F-Distribution
 - Numerator df: k 1 (k = number of groups)
 - Denominator df: k(n 1)
 - n = # observations in each group
- $F = \frac{MS_T}{MS_E}$ is called the F-Statistic.

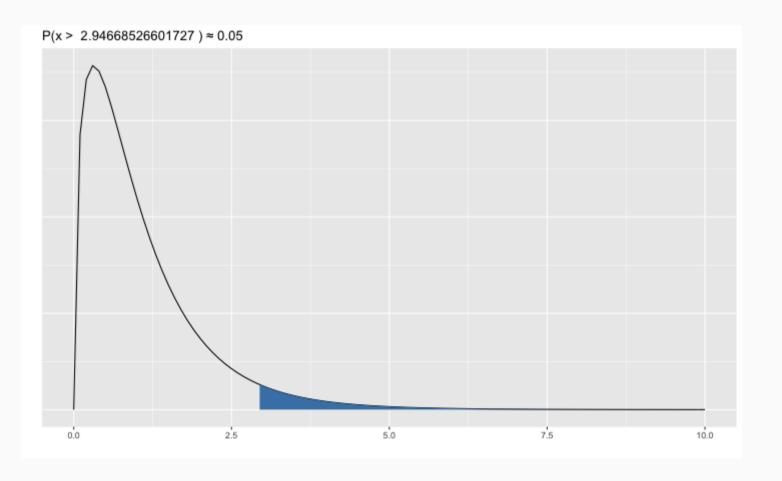

A Shiny App by Dr. Dudek to explore the F-Distribution:

https://shiny.rit.albany.edu/stat/fdist/

The F-Distribution (cont.)

```
df.numerator <- 4 - 1
df.denominator <- 4 * (8 - 1)
F_plot(df.numerator, df.denominator, cv = qf(0.95, df.numerator, df.denominator))</pre>
```

ANOVA Table

Source	Sum of Squares	df	MS	F	р
Between Group (Treatment)	$\sum_k n_k (ar{x}_k - ar{x})^2$	k - 1	$rac{SS_{between}}{df_{between}}$	$rac{MS_{between}}{MS_{within}}$	area to right of $F_{k-1,n-k}$
Within Group (Error)	$\sum_k \sum_i (ar{x}_{ik} - ar{x}_k)^2$	n - k	$rac{SS_{within}}{df_{within}}$		
Total	$\sum_k \sum_i (ar{x}_{ik} - ar{x})^2$	n - 1			

ANOVA Steps

[1] 69366

## [1] 0.001111464
```

P-value for $F_{3,28}pprox 0.0011$

F Distribution

DATA606::F_plot(df.numerator, df.denominator, cv = f.stat)

Assumptions and Conditions

- To check the assumptions and conditions for ANOVA, always look at the side-by-side boxplots.
 - Check for outliers within any group.
 - Check for similar spreads.
 - Look for skewness.
 - Consider re-expressing.
- Independence Assumption
 - Groups must be independent of each other.
 - Data within each group must be independent.
 - Randomization Condition
- Equal Variance Assumption
 - In ANOVA, we pool the variances. This requires equal variances from each group: Similar Spread Condition.

ANOVA in R

```
aov.out <- aov(Bacterial.Counts ~ Method, data=hand)
summary(aov.out)</pre>
```

What Next?

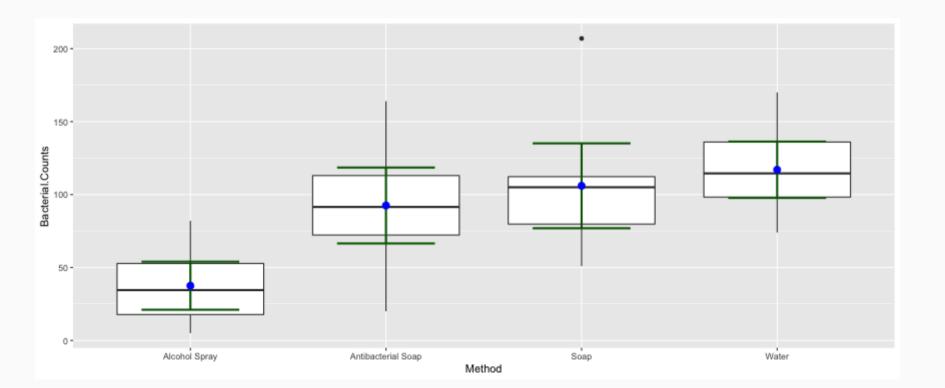

- P-value large -> Nothing left to say
- P-value small -> Which means are large and which means are small?
- We can perform a t-test to compare two of them.
- We assumed the standard deviations are all equal.
- Use s_p , for pooled standard deviations.
- Use the Students t-model, df = N k.
- If we wanted to do a t-test for each pair:
 - P(Type I Error) = 0.05 for each test.
 - Good chance at least one will have a Type I error.

• Bonferroni to the rescue!

- \circ Adjust a to α/J where J is the number of comparisons.
- \circ 95% confidence (1 0.05) with 3 comparisons adjusts to (1-0.05/3) pprox 0.98333.
- Use this adjusted value to find t**.

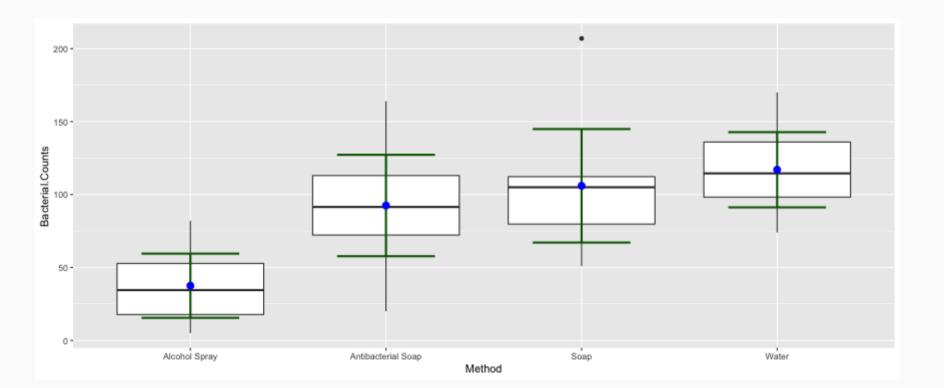

Multiple Comparisons (no Bonferroni adjustment)

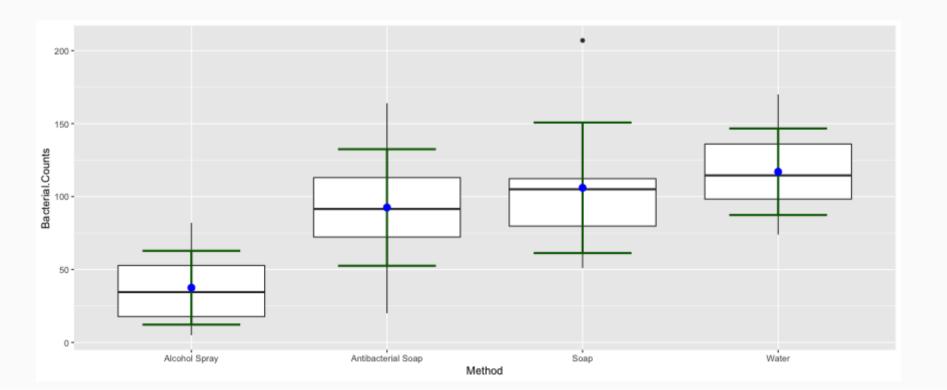

Multiple Comparisons (3 paired tests)

Multiple Comparisons (6 paired tests)
